# **GD.** Convergence rates

$$\min_{x \in \mathbb{R}^n} f(x) \qquad x_{k+1} = x_k - \alpha_k \nabla f(x_k) \qquad \kappa = \frac{L}{\mu}$$

	smooth & convex	smooth & strongly convex (or PL)
Upper bound	$f(x_k) - f^* \approx \mathcal{O}\left(\frac{1}{k}\right)$	$  x_k - x^*  ^2 \approx \mathcal{O}\left(\left(\frac{\kappa - 1}{\kappa + 1}\right)^k\right)$
Lower bound	$f(x_k) - f^* \approx \Omega\left(\frac{1}{k^2}\right)$	$  x_k - x^*  ^2 \approx \mathcal{O}\left(\left(\frac{\kappa - 1}{\kappa + 1}\right)^k\right)$ $  x_k - x^*  ^2 \approx \Omega\left(\left(\frac{\sqrt{\kappa} - 1}{\sqrt{\kappa} + 1}\right)^k\right)$

 $f \to \min_{x,y,z}$  Lecture recap

## Three update schemes

#### Normal gradient

$$\boldsymbol{x}_k - \alpha_k \nabla f(\boldsymbol{x}_k)$$

Move the point  $x_k$  in the direction  $-\nabla f(x_k)$  for  $\alpha_k \|\nabla f(x_k)\|$  amount.

₩ 0 0

## Three update schemes

Normal gradient

$$x_k - \alpha_k \nabla f(x_k)$$

Move the point  $x_k$  in the direction  $-\nabla f(x_k)$  for  $\alpha_k ||\nabla f(x_k)||$  amount.

Polyak's Heavy Ball Method

$$\boldsymbol{x}_k - \alpha_k \nabla f(\boldsymbol{x}_k) + \beta_k (\boldsymbol{x}_k - \boldsymbol{x}_{k-1})$$

Perform a GD, move the updated-x in the direction of the previous step for  $\beta_k ||x_k - x_{k-1}||$  amount.

 $f \to \min_{x,y,z}$  Lecture recap

## Three update schemes

Normal gradient

$$x_k - \alpha_k \nabla f(x_k)$$

Move the point  $x_k$  in the direction  $-\nabla f(x_k)$  for  $\alpha_k ||\nabla f(x_k)||$  amount.

Polyak's Heavy Ball Method

$$\boldsymbol{x}_k - \alpha_k \nabla f(\boldsymbol{x}_k) + \beta_k (\boldsymbol{x}_k - \boldsymbol{x}_{k-1})$$

Perform a GD, move the updated-x in the direction of the previous step for  $\beta_k ||x_k - x_{k-1}||$  amount.

Nesterov's acceleration

$$\mathbf{x}_k - \alpha_k \nabla f(\mathbf{x}_k + \beta_k(\mathbf{x}_k - \mathbf{x}_{k-1})) + \beta_k(\mathbf{x}_k - \mathbf{x}_{k-1})$$

Move the not-yet-updated-x in the direction of the previous step for  $\beta_k ||x_k - x_{k-1}||$  amount, perform a GD on the shifted-x, then move the updated-x in the direction of the previous step for  $\beta_k \| \boldsymbol{x}_k - \boldsymbol{x}_{k-1} \|$ .

## **HBM** for a quadratic problem

#### Question

Which step size strategy is used for GD?

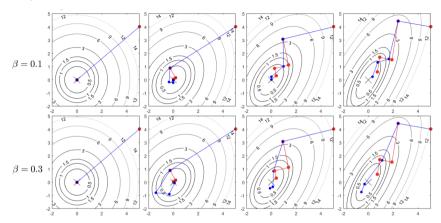

Figure 1: GD vs. HBM with fixed  $\beta$ .

**Observation:** for nice f (with spherical level sets), GD is already good enough and HBM adds a little effect. However, for bad f (with elliptic level sets), HBM is better in some cases.

## **HBM** for a quadratic problem

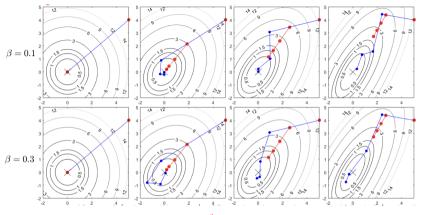

Figure 2: GD with  $\alpha = \frac{1}{r}$  vs. HBM with fixed  $\beta$ .

**Observation:** same. If nice f (spherical lv. sets), GD is already good enough. If bad f (with elliptic lv. sets), HBM is better in some cases.

### NAG as a Momentum Method

• Start by setting  $k=0, a_0=1, x_{-1}=y_0, y_0$  to an arbitrary parameter setting, iterates

Gradient update 
$$x_k = y_k - \alpha_k \nabla f(y_k)$$
 (1)

Extrapolation weight 
$$a_{k+1} = \frac{1 + \sqrt{1 + 4a_k^2}}{2}$$
 (2)

Extrapolation 
$$\boldsymbol{y}_{k+1} = \boldsymbol{x}_k + \frac{a_k - 1}{a_{k+1}} (\boldsymbol{x}_k - \boldsymbol{x}_{k+1})$$
 (3)

Note that here fix step-size is used:  $\alpha_k = \frac{1}{L} \ \forall k$ .

• Theorem. If f is L-smooth and convex, the sequence  $\{f(x_k)\}_k$  produced by NAG convergences to the optimal value  $f^*$  as the rate  $\mathcal{O}(\frac{1}{k\cdot 2})$  as

$$f(\boldsymbol{x}_k) - f^* \le \frac{4L\|\boldsymbol{x}_k - \boldsymbol{x}^*\|^2}{(k+2)^2}$$

 The above representation is difficult to understand, so we will rewrite these equations in a more intuitive manner.

# NAG as a Momentum Method

If we define

on 1 as follows using 
$$lpha_k=lpha_{k-1}$$
:

which can be used to rewrite Equation 1 as follows using  $\alpha_k = \alpha_{k-1}$ :

 $x_k = x_{k-1} + \beta_{k-1} v_{k-1} - \alpha_{k-1} \nabla f(x_{k-1} + \beta_{k-1} v_{k-1})$ 

where Equation 7 is a consequence of Equation 4. Alternatively:

then the combination of Equation 3 and Equation 5 implies:

$$-1v_{k-1} - \alpha_{k-1}\nabla f(\boldsymbol{x}_{k-1})$$

 $v_k \equiv x_k - x_{k-1}$  $\beta_k \equiv \frac{a_k - 1}{a_{k+1}}$ 

 $y_k = x_{k-1} + \beta_{k-1} v_{k-1}$ 

$$v_k = \beta_{k-1} v_{k-1} - \alpha_{k-1} \nabla f(x_{k-1} + \beta_{k-1} v_{k-1})$$

$$\mathbf{v}_{k+1} \equiv \beta_k \mathbf{v}_k - \alpha_k \nabla f(\mathbf{x}_k + \beta_k \mathbf{v}_k)$$

where  $\alpha_k > 0$  is the learning rate,  $\beta_k$  is the momentum coefficient. Compare HBM with NAG.

 $f \to \min_{x,y,z}$  NAG for DL

 $\boldsymbol{x}_{k+1} = \boldsymbol{x}_k + \boldsymbol{v}_{k+1}$

## NAG for a quadratic problem

Consider the following quadratic optimization problem:

$$\min_{x \in \mathbb{R}^d} q(x) = \min_{x \in \mathbb{R}^d} \frac{1}{2} x^\top A x - b^\top x, \text{ where } A \in \mathbb{S}^d_{++}.$$

Every symmetric matrix  $\boldsymbol{A}$  has an eigenvalue decomposition

$$A = Q \operatorname{diag}(\lambda_1, \dots, \lambda_n) Q^T = Q \Lambda Q^T, \quad Q = [q_1, \dots, q_n].$$

and, as per convention, we will assume that the  $\lambda_i$ 's are sorted, from smallest  $\lambda_1$  to biggest  $\lambda_n$ . It is clear, that  $\lambda_i$  correspond to the **curvature** along the associated eigenvector directions.

We can reparameterize q(x) by the matrix transform Q and optimize y=Qx using the objective

$$p(y) \equiv q(x) = q(Q^{\top}y) = y^{\top}Q(Q^{\top}\Lambda Q)Q^{\top}y/2 - b^{\top}Q^{\top}y = y^{\top}\Lambda y/2 - c^{\top}y,$$

where c = Qb.

We can further rewrite p as

$$p(y) = \sum_{i=1}^{n} [p]_i([y]_i),$$

where  $[p]_i(t) = \lambda_i t^2 / 2 - [c]_i t$ .

## NAG for a quadratic problem

# Theorem 2.1 from [1].

Let  $p(y) = \sum_{i=1}^n [p]_i([y]_i)$  such that  $[p]_i(t) = \lambda_i t^2/2 - [c]_i t$ . Let  $\alpha$  be arbitrary and fixed. Denote by  $\mathsf{HBM}_x(\beta, p, y, v)$  and  $\mathsf{HBM}_v(\beta, p, y, v)$  the parameter vector and the velocity vector respectively, obtained by applying one step of  $\mathsf{HBM}$  (i.e., Eq. 1 and then Eq. 2) to the function p at point p, with velocity p, momentum coefficient p, and learning rate p. Define  $\mathsf{NAG}_x$  and  $\mathsf{NAG}_v$  analogously. Then the following holds for p is p in the following holds for p in the following holds for p is p in the following holds for p is the following holds for p in the f

$$\begin{aligned} \mathsf{HBM}_z(\beta,p,y,v) &= \begin{bmatrix} \mathsf{HBM}_z(\beta,[p]_1,[y]_1,[v]_1) \\ &\vdots \\ \mathsf{HBM}_z(\beta,[p]_n,[y]_n,[v]_n) \end{bmatrix} \\ \mathsf{NAG}_z(\beta,p,y,v) &= \begin{bmatrix} \mathsf{HBM}_z(\beta(1-\alpha\lambda_1),[p]_1,[y]_1,[v]_1) \\ &\vdots \\ \mathsf{HBM}_z(\beta(1-\alpha\lambda_n),[p]_n,[y]_n,[v]_n) \end{bmatrix} \end{aligned}$$

**♥ ೧ 0** 

# NAG for a quadratic problem. Proof (1/2)

#### Proof:

It's easy to show that if

$$x_{i+1} = \mathsf{HBM}_x(\beta_i, [q]_i, [x]_i, [v]_i)$$
  
 $v_{i+1} = \mathsf{HBM}_v(\beta_i, [q]_i, [x]_i, [v]_i)$ 

then for  $y_i = Qx_i, w_i = Qv_i$ 

$$\begin{aligned} y_{i+1} &= \mathsf{HBM}_x(\beta_i, [p]_i, [y]_i, [w]_i) \\ w_{i+1} &= \mathsf{HBM}_v(\beta_i, [p]_i, [y]_i, [w]_i) \end{aligned}$$

. Then, consider one step of  $\mathsf{HBM}_v$ :

$$\begin{split} & \mathsf{HBM}_v(\beta, p, y, v) = \beta v - \alpha \nabla p(y) \\ &= (\beta[v]_1 - \alpha \nabla_{[y]_1} p(y), \dots, \beta[v]_n - \alpha \nabla_{[y]_n} p(y)) \\ &= (\beta[v]_1 - \alpha \nabla[p]_1([y]_1), \dots, \beta[v]_n - \alpha \nabla[p]_n([y]_n)) \\ &= (\mathsf{HBM}_v(\beta_1, [p]_1, [y]_1, [v]_1), \dots, \mathsf{HBM}_v(\beta_i, [p]_i, [y]_i, [v]_i)) \end{split}$$

This shows that one step of  $\mathsf{HBM}_v$  on p is precisely equivalent to n simultaneous applications of  $\mathsf{HBM}_v$  to the one-dimensional quadratics  $[p]_i$ , all with the same  $\beta$  and  $\alpha$ . Similarly, for  $\mathsf{HBM}_x$ .

# NAG for a quadratic problem. Proof (2/2)

Next we show that NAG, applied to a one-dimensional quadratic with a momentum coefficient  $\beta$ , is equivalent to HBM applied to the same quadratic and with the same learning rate, but with a momentum coefficient  $\beta(1-\alpha\lambda)$ . We show this by expanding NAG $_v(\beta,[p]_i,y,v)$  (where y and v are scalars):

$$\begin{split} \mathsf{NAG}_v(\beta,[p]_i,y,v) &= \beta v - \alpha \nabla[p]_i(y+\beta v) \\ &= \beta v - \alpha (\lambda_i(y+\beta v) - c_i) \\ &= \beta v - \alpha \lambda_i \beta v - \alpha (\lambda_i y - c_i) \\ &= \beta (1-\alpha \lambda_i) v - \alpha \nabla[p]_i(y) \\ &= \mathsf{HBM}_v(\beta (1-\alpha \lambda_i),[p]_i,y,v). \end{split}$$

QED.

#### Observations:

- HBM and NAG become **equivalent** when  $\alpha$  is small (when  $\alpha\lambda\ll 1$  for every eigenvalue  $\lambda$  of A), so NAG and HBM are distinct only when  $\alpha$  is reasonably large.
- When  $\alpha$  is relatively large, NAG uses smaller effective momentum for the high-curvature eigen-directions, which **prevents oscillations** (or divergence) and thus allows the use of a larger  $\beta$  than is possible with CM for a given  $\alpha$ .

Figure 3: The table reports the squared errors on the problems for each combination of  $\beta_{max}$  and a momentum type (NAG, CM). When  $\beta_{max}$  is 0 the choice of NAG vs CM is of no consequence so the training errors are presented in a single column. For each choice of  $\beta_{max}$ , the highest-performing learning rate is used. The column SGD $_C$  lists the results of Chapelle & Erhan (2011) who used 1.7M SGD steps and tanh networks. The column HF $^{\dagger}$  lists the results of HF without L2 regularization; and the column HF $^*$  lists the results of Martens (2010).
